INTRODUCTION

This volume contains the Results of the meteorological observations made at the Madras Observatory in the years 1861-1890 during the whole of which time, with the exception of the first few weeks, the late NORMAN ROBERT Pogson was Government Astronomer and had charge of the Observatory. It was his intention to have published this volume as soon as possible after the completion of the 30 years, and at the time of his lamented death a considerable part of the manuscript was nearly ready for the press. In editing the work I have, so far as possible, retained the original plan, but I greatly regret that the work was not completed by one who had carried it on so long and to whose care and knowledge it owes its main value. Begun at a time when accurate meteorological observations were less common than they are now and when instrumental appliances were far from perfect, the whole series has been carried out with that scrupulous accuracy and attention to details which his astronomical training had shown Mr. Pogson to be an essential for all really good work. All work connected with the testing of the instruments and working out the corrections was done by himself, while the whole of the work was rigidly supervised. This being so it is all the more to be regretted that he was not able to publish the results and to give a full account of the methods employed. Of his methods for checking the results I learned a good deal from him in conversation from time to time, but in preparing this Introduction I have frequently felt at a loss with regard to minor details which I cannot find amongst the voluminous papers in the Observatory. At the same time the results may be taken as being as nearly as possible accurate for they were reduced immediately after they were taken and all needful corrections were at once applied, so that with the exception of the actual printing and the notes the results had received Mr. Pogson's final revision before his death. Even the notes are mostly taken with a few modifications from his remarks in the Government Gazette in which the weekly, monthly, and annual results have been published since 1870. The only results that I have found it necessary to re-calculate were those for humidity and vapour pressures, the latter of which were, for most of the period dealt with, not calculated at the time but only prepared for this work and not revised. With the exception of the first few months I have re-calculated these throughout from the printed sheets. All the averages have also been taken out fresh from the printed sheets and compared with the manuscript results, so that there seems little risk of any serious error in the printed means.

Instruments.

(1) Barometer.—From January 1861 to December 1876 the barometer employed was the old Observatory standard, Newman No. 42. It was, as formerly, used with a fixed zero of 29.900 inches and the readings were corrected for capacity. The diameter of the tube is 0.514 inches, its thickness 0.125 inches, and the diameter of the cistern is 2.64 inches. When compared in London in 1840, before despatch to Madras, it read 0.005 inches higher than the flint glass standard of the Royal Society, or 0.012 inches higher than the

iv introduction

crown glass standard. No correction has been applied for this difference. From January 1877 to January 1888 the instrument employed was Newman's standard No. 49. This is an instrument similar to Newman No. 42 but with a tube 0.532 inches in diameter. The two barometers were compared by 30 readings in June 1876 and 20 readings in January 1877 which yielded a mean zero correction of +0.012 inches, which was applied to all the readings. From January 1888 onwards the standard barometer was a secondary standard by Casella (No. 636). It is a Fortin's cistern barometer and the zero is adjusted before each reading. The readings of this barometer do not seem to me to be thoroughly satisfactory, but it is possible that during the time dealt with in the volume there was no cause for complaint, and even at present I do not think that on any day the mean reading is as much as 0.01 inches wrong. The relative correction between this and another similar barometer has changed by only 0.001 inches. The fact that the mean barometer reading for the 30 years differs by only 0.001 inches from the mean obtained from the hourly readings for the preceding 20 years shows that the relative corrections of the other two barometers to the standard of Newman No. 42 have been made with great accuracy.

(2) Thermometers.—The dry and wet bulb thermometers have all been carefully compared from time to time with standard thermometers and the freezing points of the standards have themselves been checked in melting ice. The two standards employed were Kew 328 and Kew 329. The zero of the former was determined in 1865, 1872, and 1874 and on each occasion was found to be exactly right. This thermometer was accidentally broken by coming in contact with the punkah just after the last comparison was made. Kew 329 was less constant. The following are the freezing point determinations made with it:

 1865 ... 31·90
 1876 ... 31·50

 1874 ... 31·50
 1877 ... 31·50

 1875 ... 31·55

It has been used since 1874 with the correction +0.5. It is rather remarkable that the freezing point has fallen. The corrections for the other thermometers were determined in the following way. For the dry maximum the correction was taken as the difference of readings at 10 a.m. between the dry bulb (corrected) and the dry maximum. For the dry minimum the correction was taken as the difference of reading at 10 p.m., (or latterly 8 p.m.) between the dry bulb (corrected) and the dry minimum. The corrections for the wet minimum and grass minimum were similarly got by comparison with the wet bulb at 10 p.m., and the corrections for the sun maximum also by comparison with the dry bulb at the same hour. The evening and not the morning reading being taken in this case on account of the very unsatisfactory nature of comparisons that are made of sun thermometers in vacuo in day-light, and because the thermometer should be exposed long before 10 a.m. In each case the actual correction applied for each half month was the mean of the corrections obtained for that half month.

Anemograph.—Since 1864 the wind direction and velocity have been obtained from the records of a Beckley anemograph, by Adie, carried on a wooden framework erected on the roof of the Astronomer's house. The cups of the anemograph are about $8\frac{1}{4}$ inches in diameter and the distance from centre to centre of two opposite cups is 4 feet. The height of the cups above ground is 44 feet and the height above the parapet of the building is 18 feet. I can find no record of any tests that were made as to the accuracy of the scale of this instrument before it was sent to Madras, but as it was made under the direction of the late Professor Balfour Stewart it is probable that due care was taken regarding this important point. The readings for wind velocity have been accepted without any correction, and the instrument has been taken as the standard for smaller instruments used in other parts of the Presidency. The accuracy as regards wind direction has been tested from time to time. The record of direction is not thoroughly trustworthy when the velocity falls below two miles an hour.

INTRODUCTION

Raingauges.—The standard raingauge has a funnel 8 inches in diameter and the mouth is two feet above the surface of the ground. The gauge and measuring glass have been carefully tested. The distribution of the rainfall between the hours of reading is effected by reference to the raingauge connected with the anemograph. This consists of a receiver nearly 15 inches in diameter connected by a long pipe with a cylindrical receiver in which there is a float. This float actuates a pencil which records the rainfall on the revolving drum of the anemograph. When the receiver is filled up to a certain point it is emptied by a siphon on the principle of the tantalus cup. This arrangement is far from satisfactory, especially in a light rain, for at times the siphon does not act suddenly but the water only dribbles out at the same rate as it comes in. In heavy rain the action is fairly good. It should be noted, however, that any failure in the action of this gauge does not affect the total amount registered but only the hourly distribution. The total fall registered is that given by the standard gauge. The real risk in rainfall measurements is in miscounting the number of fills of the measuring glass and this risk has been guarded against by always measuring the amount in two other gauges of different sizes.

Position of Instruments.

The barometer is hung on the north wall of the transit room and the cistern is 22 feet above mean sea level. The readings given in this volume have not been reduced to sea level, neither has any correction been applied for the value of gravity. To reduce to sea level and the value of gravity at latitude 45° the following corrections have to be applied:—

Barometer	T	emperature	F°
Inches.	70°	80°	90°
29	-0.044	-0.044	-0.045
30	-0.046	-0.046	-0.047
31	-0.048	-0.048	-0.049

Previous to 1861 the thermometers were exposed in a large open verandah with a tiled roof, but as this evidently did not meet the requirements of exact shade temperature measurements Mr. Possox introduced what is now known as the "Indian shed" and used, I believe, at all Indian observatories. The shed, which lies north and south, consists of a thatched gable roof supported on wooden posts and frames with a light railing round it to keep out cattle. The shed is 16 feet long and 12 feet broad; the roof is 5 feet from the ground at the sides and 10 feet at the middle. The sides and ends are quite open except for two side screens $5\frac{1}{2}$ feet wide, reaching from the roof to within 1 foot of the ground, in the centre of the sides. The thatch is 6 inches thick. Originally the thermometers, which face north, were fixed to an open frame in the centre of the shed but for some years past, to protect them from injury from crows and other animals, they have been placed in a light cage of which the back and front are made of very wide-meshed iron wire netting. The bulbs of the wet and dry bulb thermometers are 4 feet from the ground, those of the dry maximum and dry minimum 4 feet 7 inches and 4 feet 4 inches respectively. The wet and dry bulb thermometers are at opposite sides of the cage and are 16 inches apart. The door of the cage is hinged at the bottom so that when open the thermometers are fully exposed. The door is always opened five minutes before readings are taken. In front of the shed, in a space enclosed by a wire fence, are the rainganges and the latter 3 inches above the surface of the ground.

vi

The ground inside the enclosure and all round it is covered with grass in the wet season but in the hot weather there is frequently little grass to be seen.

This form of thermometer shelter is perhaps not altogether an ideal one but it is incomparably superior to the Stevenson or other similar screens still used even in some tropical or semi-tropical countries. In fact Dr. Doberek has recently shown by a long series of comparisons with rotating thermometers, carried out at Hongkong, that the Indian shed is far the best screen in common use. So far as I have been able to determine, the errors are very small except on perfectly still, bright days when even the slight hindrance which it offers to the free circulation of the air produces appreciable differences between the air temperatures outside and inside the shed. The highest temperatures recorded are probably not at all affected by this, for they occur when there is a strong dry wind blowing from the west.

It will be noticed from the table on p. 392 that the mean thermometric range and the mean maximum temperatures for the 30 years 1861 to 1890 differ considerably from those for the 20 years preceding. This is due to the change in the method of exposure. Comparative readings of thermometers in the verandah and in the shed were taken for a sufficiently long time to enable the relative corrections to be determined with accuracy, and when these corrections are applied to the 20 years' series the means come out almost exactly the same as those for the 30 years' series.

Hours of Reading and Methods of Reduction.

From 1841 to 1860 the readings were taken at each hour of Göttingen mean time, but from 1861 Madras mean time was employed. From 1861 to 1889 the hours of reading were 10 a.m., 4 p.m., and 10 p.m., and thereafter, on account of a change in the hour of sending the daily weather telegram to Simla, the hours were 8 a.m., 2 p.m., and 8 p.m. The method of deducing the means from the observations differs from that usually employed and must therefore be described more in detail. It must be remembered that in India the daily barometer tide is the most prominent feature in the barometric readings, and no reduction is of any value which does not pay due attention to this. Were the tide perfectly uniform the correction for hours might be treated as a constant which had to be added to or subtracted from the mean reading, but the amount of the tide varies from day to day and Mr. Pogson held that the true correction for hours in any day was a function of the tide for that day. Accordingly the first thing to be determined is the daily range. The hours of maximum and minimum readings are near 10 a.m. and 4 p.m., but do not exactly coincide with them, and so the range is got by multiplying the difference between the 10 a.m. and 4 p.m. readings by a factor which varies slightly from month to month and is called the Barometric Range Factor. The range having been thus determined the correction for hours is got by multiplying it by a factor depending on the season of the year and the hours of observation. An exactly similar treatment is applied to the thermometer readings.

The following extract from Mr. Pogson's Meteorological Reduction Tables will show the actual method employed:—

"The hours of registration adopted throughout the Madras Presidency are 10 A.M., 4 P.M., and 10 P.M. The barometric range is found, by multiplying the difference between the 10 A.M. and 4 P.M. readings, both previously reduced to 32°, by the factor for the date, taken from the column headed Barometric Range, retaining only three decimal places. The daily range thus found when multiplied by the factor in the next column, headed Mean Barometer, gives the correction, always minus or subtractive from the mean of the three reduced readings, to obtain the mean atmospheric pressure for the day.

The numbers in the column headed Dry Bulb Thermometer, are factors by which to multiply the range, or difference between the corrected readings of the maximum and minimum dry bulb thermometers, retaining only tenths of a degree in the product. The mean of the morning minimum, and of the three ordinary readings, i.e., their sum divided by four, when diminished by this small correction, gives the mean daily temperature. From August 9th till September 28th there is no correction at all, the factor being 0.00; and for nearly all the rest of the year, as the factor is only -0.01, the correction will be found by simply removing the decimal point two places to the left in the range for the day, retaining the nearest tenth of a degree in the usual manner.

For the mean daily temperature of evaporation the process is very similar; only in this case, the range not being known, the factor for the day, taken from the column Wet Bulb Thermometer, is to be multiplied by the excess of the 4 P.M. reading above that of the morning minimum; and the correction is always plus, or additive to the mean of the four readings."

All these factors have been calculated from the series of hourly observations made between 1841 and 1861 of which the first 15 years have been published but the last 5 years are still in manuscript. The following is the actual table used when the readings were 10 A.M., 4 P.M. and 10 P.M.:—

Moisture.—The vapour tension (I use the term under protest) and humidity have been calculated from Blanford's Tables for the Reduction of Meteorological Observations in India.

Wind.—The mean daily direction of the wind was obtained simply by taking the arithmetical mean of the mean directions for each hour as measured on the anemogram. Similarly the mean monthly and annual directions are the arithmetical means of the daily and monthly means. A separate table is given at the end showing the resultant monthly and annual wind direction and force got by taking account of the number of miles of wind from each point of the compass from 1868 to 1890.

Rainy days.—The number of rainy days given is got by reckoning all days on which 0.01 of an inch

VIII INTRODUCTION

and upwards fell. This must be remembered in comparing with other Indian returns in which a day is not counted unless 0.1 of an inch falls. The rain recorded is for the civil day—midnight to midnight.

Clouds.—The cloud proportion is obtained from eye estimates made three times a day. This is probably the least satisfactory of all the records and can be looked upon as only a very rough approximation to the truth. This is especially the case with the records since 1887 when night observations by the assistants were given up. After that no account was taken of the cloudiness between the hour of the evening observation and about 8 A.M. of the following day. I have not printed the records of the character of the clouds partly because Mr. Pocson had not intended to do so in the part of the volume he had prepared, and partly because of the very unsatisfactory nature of the records.

General Weather.—This has been taken from the weather remarks in the observation books up to 1870, and thereafter from the "General Weather" column in the weekly Gazette notices. It is of very little value but I have utilized it for recording thunder and lightning. With regard to this it may be pointed out that the term 'thunderstorm' is employed only when there was thunder and lightning accompanied by rain. In cases in which the entry is "thunder: lightning: rain", the rain did not accompany the thunder and lightning.

GENERAL REMARKS.

It was at first intended to add to this volume a series of appendices discussing the observations, but I have thought it better to issue the volume as it is, leaving over all discussion till it is possible to take up the records for the complete period of 50 years from 1841 to 1890. Before this is done it will probably be well to publish the hourly observations for the five years 1856-1860. Meanwhile the tables of averages at the end of the volume will give a very close approximation to the true, mean meteorological conditions of Madras, for the period of 30 years seems to be long enough to eliminate both accidental and cyclical variations.

I cannot conclude this Introduction without expressing my admiration at the skill and thoroughness with which Mr. Pogson organised and carried out these observations. The immense amount of labour which he bestowed on the investigation of the corrections that had to be applied to obtain true mean values is proved by the masses of papers which he left on the subject, and some idea of it may be obtained from the consideration that in the matter of temperatures at least all the old observations had to be corrected not only for instrumental errors but also for defective exposures before they could be utilized for this purpose. The success with which these corrections were applied may be judged from the fact that the means deduced in 1868 agree almost exactly with the means now got for the 30 years. Unfortunately, the whole of this work had to be done by Mr. Pogson himself so that none of the assistants know anything of the methods employed, hence though the results are available it is not always easy to find how they were arrived at, and other work has prevented me from going into the question as thoroughly as I would have wished to have done.

Note.—The Cyclone reached the Nellore coast on the morning of the 21st. The greatest force of the wind at Madras was 43 miles per hour (S. S. W.): the lowest reading of the harometer (reduced) was 29·152 between 4-30 a.m. and 5-30 a.m. on the 21st. Rain fell during 29 hours, continuously from 6 a.m. on the 20th to 9 a.m. on the 21st, but the rate never exceeded 0·41 inches per hour.

Note.—12th & 13th.—This cyclone was accompanied by a very high sea which did great damage to the Madras Harbour, but the wind at no time reached a very great velocity. The centre passed to the south of Madras. The lowest reading of the barometer was 29.51 at 4 p.m. on the 12th, and the strongest wind was between 11 p.m. on the 12th and 2 A.M. on the 13th, when it averaged 32 miles per hour. The rain was continuous from 1-30 A.W. to 8 p.m. on the 12th.

Note.—21st. The southern portion of a somewhat severe cyclone swept over Madras between 3 A.M. and noon. At midnight the barometer reading (reduced) was 29.77, wind N. W. 19 miles per hour. At 4-45 A.M. the wind was due west 28 miles an hour and the barometer 29.61 inches. At 7 A.M. the wind was S. W. and the barometer had reached its lowest point, 29.57 inches. Between 7 and 8 A.M. the wind velocity was 49 miles per hour and the direction oscillated wildly between S.W. by W. and S. by W. During one of the gasts the thermometer shed was blown down. This cyclone is chiefly remembered by the circumstance that it burst the Red Hills' tank from which Madras obtains its water supply. The wind was at its height when the direction was along the greatest length of the tank and the waves thus produced washed away part of the embankment.

Madras Meteorological Observations. 1884-December.

Note.—9th.—This cyclone was one of considerable severity. The centre struck the coast about 50 miles N. of Madras and the storm crossed the Peninsula and the Arabian Sea. The lowest barometric pressure at Madras was 29.251 (reduced) at 1 p.m., and the maximum wind velocity was 45 miles per hour. For an account of the storm, see Indian Meteorological Memoirs, Vol. IV., Part IV.

Note—The cyclene recorded on the 31st prevailed more or less throughout the 30th and 31st October and the 1st November. The rain commenced at 9 r.m. on the 29th and was heavily continuous for the next forty-eight hours, during which time over 14 inches were collected. It almost entirely ceased about an hour before the middle of the storm. The cyclene proper, as indicated by falling baremeter and rising wind, may be said to have begun about 2 r.m. on the 30th. It reached its maximum force between 8 and 9 r.m. on the 31st, nearly an hour before the time of lowest pressure, which was almost exactly at 10 r.m., when the wind moderated for about three hours, afterwards rising considerably between 1 and 4 r.m. on the 1st November, and only

becoming ordinary by noon on that day. The lowest barometric pressure reduced to 32° was 28°995 inches and the greatest hourly wind volocity 46 miles. The gusts were, however, unquestionably stronger than in the memorable cyclone of May 1872, when the maximum hourly velocity was actually seven miles greater. One of the gusts blew over a train on the South India Railway. The centre of the cyclone passed between the Observatory and the Marine Office. See Cyclone Memoirs, Part 111.
